

Thickness Mapping of Retinal Layers by Spectral-Domain Optical Coherence Tomography

ANA L. LODUCA, CHI ZHANG, RUTH ZELKHA, AND MAHNAZ SHAHIDI

• **PURPOSE:** To report normal baseline thickness maps for 6 retinal layers generated by segmentation of spectral-domain optical coherence tomography (SD-OCT) images in normal subjects. Intersubject thickness variability and thickness variations in 9 macular sectors were established.

• **DESIGN:** Prospective cross-sectional study.

• **MATERIALS AND METHODS:** SD-OCT imaging was performed in 15 normal subjects. Nineteen SD-OCT images were acquired, encompassing a 6×5 -mm retinal area, centered on the fovea. Each image was analyzed using an automated segmentation algorithm to derive thickness profiles of 6 retinal layers. Thickness data obtained from all scans were combined to generate thickness maps of 6 retinal layers: nerve fiber layer, ganglion cell layer + inner plexiform layer, inner nuclear layer, outer plexiform layer, outer nuclear layer + photoreceptor inner segments, and photoreceptor outer segments. Mean and standard deviation of thickness measurements were calculated in 9 macular sectors and 6 retinal layers. Intersubject and intrasector thickness variations were established based on standard deviation of measurements.

• **RESULTS:** Minimum and maximum thickness of the nerve fiber layer were observed in the foveal and nasal perifoveal areas, respectively. The largest thickness variation among subjects and intrasector variability were observed in perifoveal areas. Thickness of the ganglion cell layer + inner plexiform layer and intersubject thickness variability were largest in parafoveal areas. The inner nuclear layer thickness was relatively constant in parafoveal and perifoveal areas and intrasector thickness variations were largest in the foveal area. The outer plexiform layer thickness was relatively constant in foveal and parafoveal areas and higher than in perifoveal areas. Intersubject thickness variability in inner nuclear layer and outer plexiform layer was relatively uniform in all macular sectors. The outer nuclear layer + photoreceptor inner segments thickness map displayed maximum thickness in the foveal area and intersubject thickness variability was largest superior to the fovea. Thickness of the photoreceptor outer segments layer, thickness varia-

tions among subjects, and intrasector thickness variability were relatively constant. There was a significant correlation between total retinal thickness derived by thickness mapping and SD-OCT commercial software.

• **CONCLUSION:** Normal thickness maps for 6 retinal layers were generated and thickness variations among subjects and macular areas were assessed. This technique is promising for investigating thickness changes attributable to disease in specific retinal layers and macular areas. (*Am J Ophthalmol* 2010;150:849–855. © 2010 by Elsevier Inc. OPTICAL COHERENCE TOMOGRAPHY (OCT) IS AN optical imaging technique that provides objective and quantitative measurements of retinal thickness alterations associated with retinal diseases. OCT images have been analyzed to provide maps of normal macular thickness.¹ Furthermore, segmentation of OCT images has provided information about thickness of specific retinal layers. Time-domain (TD) OCT images have been segmented to provide thickness maps of the nerve fiber layer, ganglion cell layer, inner plexiform layer, and inner nuclear layer in normal subjects and glaucoma patients.^{2,3} Additionally, thickness maps of the outer nuclear layer have been generated in normal subjects and in children with Leber's congenital amaurosis.⁴ Furthermore, ultra-high-resolution OCT imaging has been applied to measure thickness of the photoreceptor layer in normal subjects and patients with macular degeneration.^{5,6}

With the availability of spectral-domain OCT (SD-OCT), it is now possible to obtain multiple scans over a retinal area and generate quantitative maps of retinal thickness with high spatial resolution. Several studies have reported comparisons of total retinal thickness measurements obtained by TD- and SD-OCT instruments.^{7–9} Additionally, SD-OCT imaging technology has been used to measure macular thickness in normal subjects^{8,10,11} and to generate macular thickness maps of a 3-layer complex consisting of the nerve fiber layer, ganglion cell layer, and inner plexiform layer in patients with various nonglaucomatous optic neuropathies.¹² In the current study, our previously reported SD-OCT image segmentation technique¹³ was applied to SD-OCT images. Normal thickness maps of 6 retinal layers were generated and intersubject thickness variations were assessed. For each retinal layer, thickness measurements and variations in 9 macular sectors were established. Generating normal thickness maps

FIGURE 1. A representative spectral-domain optical coherence tomography image obtained in the left eye of 1 subject in the study. The 6 retinal layers were the nerve fiber layer (layer 1), ganglion cell layer + inner plexiform layer (layer 2), inner nuclear layer (layer 3), outer plexiform layer (layer 4), outer nuclear layer + photoreceptor inner segments (layer 5), and photoreceptor outer segments (layer 6).

of retinal layers and assessing thickness variations among subjects is needed to identify thickness changes that occur because of disease.

MATERIALS AND METHODS

SD-OCT IMAGING WAS PERFORMED IN 1 EYE OF 15 NORMAL subjects, 8 female and 7 male, 8 right and 7 left eyes. The subjects' ages ranged between 40 and 59 years, with an average age of 52 ± 6 years (mean \pm standard deviation).

SD-OCT imaging was performed using a commercially available OCT instrument (Spectralis, Heidelberg Engineering, Heidelberg, Germany). Nineteen horizontal SD-OCT B-scans were acquired in each eye, encompassing a 6×5 -mm retinal area, centered on the fovea. Each SD-OCT image was 1024 pixels (6 mm) in length and 496 pixels (2 mm) in depth. The grayscale SD-OCT images were exported in tagged image file format for segmentation analysis.

Each SD-OCT image was analyzed using an image segmentation algorithm and thickness profiles of 6 retinal layers were automatically generated, as previously described.¹³ A representative SD-OCT image obtained in 1 subject is shown in Figure 1. Six retinal layers were identified by the automatic segmentation algorithm: nerve fiber layer (layer 1), ganglion cell layer + inner plexiform layer (layer 2), inner nuclear layer (layer 3), outer plexiform layer (layer 4), outer nuclear layer + photoreceptor inner segments (layer 5), and photoreceptor outer segments (layer 6). The image segmentation algorithm was applied to all 19 SD-OCT images. From each image, a thickness profile for each of the 6 retinal layers was generated by averaging thickness over contiguous 240- μ m segments, along the 6-mm scan length. Layer 1 thickness profiles derived from all images were combined to generate a thickness map of layer 1. This procedure was repeated for each of the 6 retinal layers. Thickness maps of the 6 retinal layers were displayed in pseudo-color. Total retinal thick-

FIGURE 2. Thickness data from the map of each layer were grouped in 9 macular sectors, within 3 concentric circles. The retinal areas encompassed by 9 macular sectors are displayed on a fundus photograph.

ness was also calculated by summing thickness measurements in the 6 layers.

From the retinal layer thickness map, data were grouped in 9 macular sectors within 3 concentric circles as defined by the Early Treatment Diabetic Retinopathy Study.¹⁴ The retinal areas encompassed by the 9 macular sectors are displayed in Figure 2. In each subject, the location of the center of fovea was first identified based on the minimum thickness on the map of layer 2 (ganglion cell layer + inner plexiform layer). This location defined the center of the concentric circles. Since the thickness data were stored in a 2-dimensional rectangular array, the horizontal dimension was used to define the diameter of the circles for grouping of data points. The central circle (sector 1) had a diameter of 1.2 mm and represented the central foveal area. The second circle had a diameter of 3.1 mm and was subdivided into superior (sector 2), nasal (sector 3), inferior (sector 4), and temporal (sector 5) parafoveal retinal areas. The third circle had a diameter of 6 mm and was subdivided into superior (sector 6), nasal (sector 7), inferior (sector 8), and temporal (sector 9) perifoveal retinal areas. Macular sectors 1, 2 to 5, and 6 to 9 contained 15, 38, and 74 data points, respectively.

From thickness maps generated in each subject, a mean and standard deviation (SD) of measurements was calculated in each of the 9 macular sectors and 6 retinal layers. Intrasector variability was defined by a mean SD of thickness measurements, averaged over all subjects. From thickness maps generated in all subjects, a mean

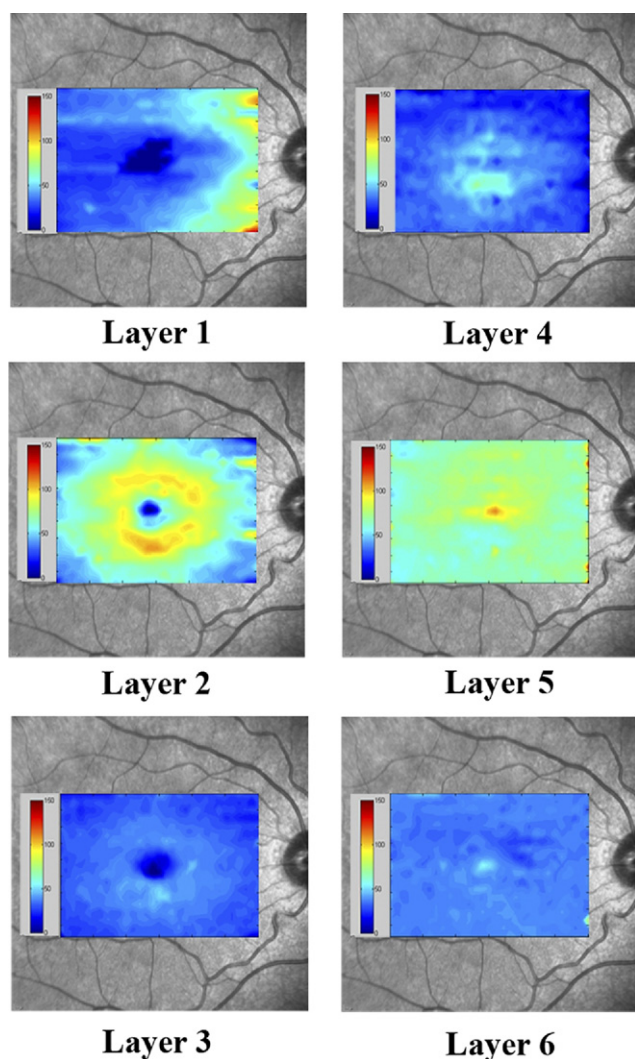

FIGURE 3. Examples of thickness maps of 6 retinal layers in a right eye of 1 subject in the study. The 6 retinal layers were the nerve fiber layer (layer 1), ganglion cell layer + inner plexiform layer (layer 2), inner nuclear layer (layer 3), outer plexiform layer (layer 4), outer nuclear layer + photoreceptor inner segments (layer 5), and photoreceptor outer segments (layer 6).

normal thickness was established in each of the 9 macular sectors and in each of the 6 layers, by averaging thickness measurements over all subjects. Intersubject variability was defined as the SD of thickness measurements in all subjects. Thickness measurements among sectors were compared in each layer using analysis of variance statistics. Total retinal thickness in each sector was calculated by summing thickness measurements in all 6 layers. In the same subjects, an average total retinal thickness in each macular sector was obtained from the Spectralis SD-OCT software. Total retinal thickness measurements, averaged over all macular sectors, obtained by automated mapping and Spectralis SD-OCT software were compared, using linear regression analysis.

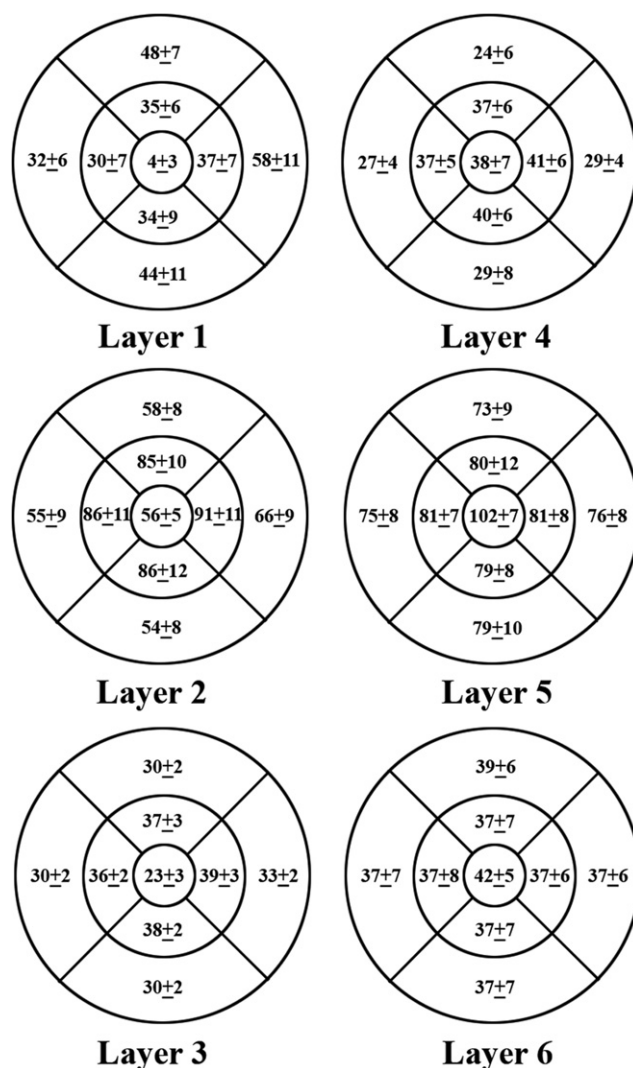

FIGURE 4. Mean normal macular sector thickness for 6 retinal layers and the corresponding standard deviations. The 6 retinal layers were the nerve fiber layer (layer 1), ganglion cell layer + inner plexiform layer (layer 2), inner nuclear layer (layer 3), outer plexiform layer (layer 4), outer nuclear layer + photoreceptor inner segments (layer 5), and photoreceptor outer segments (layer 6).

RESULTS

BY AUTOMATED SEGMENTATION OF 19 SD-OCT IMAGES, thickness maps were generated in 6 retinal layers: nerve fiber layer (layer 1), ganglion cell layer + inner plexiform layer (layer 2), inner nuclear layer (layer 3), outer plexiform layer (layer 4), outer nuclear layer + photoreceptor inner segments (layer 5), and photoreceptor outer segments (layer 6). Examples of thickness maps generated from the right eye of 1 subject are shown in Figure 3. The thickness map of layer 1 (nerve fiber layer) displayed minimum thickness in the central foveal area and maximum thickness nasal to the fovea. The thickness map of layer 2 (ganglion cell layer + inner plexiform layer) also

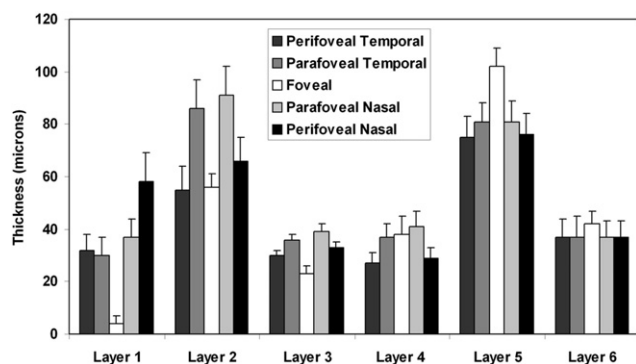

FIGURE 5. Mean and standard deviation of macular sector thickness plotted as a function of retinal eccentricity for 6 retinal layers. The 6 retinal layers were the nerve fiber layer (layer 1), ganglion cell layer + inner plexiform layer (layer 2), inner nuclear layer (layer 3), outer plexiform layer (layer 4), outer nuclear layer + photoreceptor inner segments (layer 5), and photoreceptor outer segments (layer 6).

displayed a minimum thickness in the central foveal area, but the maximum thickness was observed in a circular pattern in the parafoveal retinal area. The thickness map of layer 3 (inner nuclear layer) showed a relatively constant thickness, with the lowest thickness in the central foveal area. In the foveal and parafoveal retinal areas, thickness of layer 4 (outer plexiform layer) was highest and relatively constant, while in the perifoveal retinal area, thickness was lower and also relatively constant. Thickness of layer 5 (outer nuclear layer + photoreceptor inner segments) was highest in the central foveal area and relatively constant in the parafoveal and perifoveal retinal areas. The thickness map of layer 6 (photoreceptor outer segments) displayed a uniform thickness in all retinal areas.

Mean macular sector thickness for each of the 6 retinal layers and the corresponding SD (intersubject thickness variability) is shown in Figure 4 (displayed for a right eye). Nerve fiber layer thickness superior and inferior to the fovea was similar. A minimum thickness of the nerve fiber layer was observed in the central foveal area and a maximum thickness in the perifoveal retinal area, nasal to the fovea and closest to the optic nerve head. Thickness of the ganglion cell layer + inner plexiform layer was highest in parafoveal retinal areas, particularly nasal to the fovea. The inner nuclear layer thickness was relatively constant in all macular sectors, with a minimum thickness observed in the central foveal area. The outer plexiform layer thickness was also relatively constant in foveal and parafoveal retinal areas and higher than the uniform thickness measured in perifoveal retinal areas. The outer nuclear layer + photoreceptor inner segments thickness map displayed a maximum thickness in the central foveal area and a relatively constant thickness in the perifoveal retinal areas. Thickness of the photoreceptor outer segments layer

TABLE 1. Intrasector Thickness Variability in 9 Macular Sectors and in 6 Retinal Layers

Sector	Mean Standard Deviation (μ m)					
	Layer 1	Layer 2	Layer 3	Layer 4	Layer 5	Layer 6
Sector 1	6	25	9	11	15	5
Sector 2	11	14	4	8	9	5
Sector 3	9	11	4	6	8	5
Sector 4	11	16	4	8	6	4
Sector 5	9	13	2	6	8	4
Sector 6	16	16	6	7	9	6
Sector 7	16	18	6	10	14	7
Sector 8	15	15	6	8	11	6
Sector 9	6	14	4	7	9	7

Layer 1 = nerve fiber layer; Layer 2 = ganglion cell + inner plexiform layers; Layer 3 = inner nuclear layer; Layer 4 = outer plexiform layer; Layer 5 = outer nuclear layer + photoreceptor inner segments; Layer 6 = photoreceptor outer segments; Sector 1 = fovea; Sector 2 = parafoveal superior, Sector 3 = parafoveal nasal, Sector 4 = parafoveal inferior, Sector 5 = parafoveal temporal; Sector 6 = perifoveal superior, Sector 7 = perifoveal nasal, Sector 8 = perifoveal inferior, Sector 9 = perifoveal temporal.

was slightly higher in the central foveal area, but overall was relatively constant in all macular sectors.

Intersubject thickness variability, defined as the SD of thickness measurements in each macular sector and each retinal layer, is displayed in Figure 4. The mean and SD of thickness measurements in each retinal layer are plotted as a function of eccentricity in Figure 5. In the nerve fiber layer, the largest thickness variation among subjects was observed in the perifoveal nasal retinal area, which also had the highest mean thickness. Intersubject thickness variability of the ganglion cell layer + inner plexiform layer was largest in parafoveal retinal areas, indicating large individual variations in this region. In the inner nuclear and outer plexiform layers, thickness variations among subjects were relatively uniform across all macular sectors and also lowest compared to all other layers. Intersubject thickness variability in the outer nuclear layer + photoreceptor inner segments layer was largest superior and inferior to the fovea and relatively constant in other macular sectors. Thickness variations among subjects in all macular sectors of the photoreceptor outer segments layer were relatively constant.

Intrasector thickness variability, defined by the mean SD of thickness measurements (averaged over all subjects) in each macular sector and retinal layer, is listed in Table 1. In the nerve fiber layer, the largest intrasector variability was observed in the perifoveal retinal area superior, nasal, and inferior to the fovea. Intrasector thickness variability of the ganglion cell layer + inner plexiform layer was largest compared to all other layers. In the inner nuclear layer, intrasector thickness variation was greatest in the

FIGURE 6. Relationship between total retinal thickness (TRT) measurements derived by thickness mapping and Spectralis spectral-domain optical coherence tomography software.

central foveal area and relatively constant in all other sectors. Intrasector thickness variabilities in the outer plexiform layer and outer nuclear layer + photoreceptor inner segments layer were similar, with the largest variations observed in the central foveal area and perifoveal retinal area nasal to the fovea. In the photoreceptor outer segments layer, intrasector thickness variability was small and relatively constant in all macular sectors. Thickness measurements among 9 macular sectors were significantly different in all layers ($P < .001$), except the photoreceptor outer segments layer ($P = .5$).

The relationship between total retinal thickness derived from thickness mapping and Spectralis SD-OCT software is shown in Figure 6. There was a significant correlation between total thickness measured by thickness mapping and Spectralis SD-OCT software ($r = 0.90$, $P < .001$; $N = 15$). The best fit line relating total retinal thickness derived by the 2 methods had the following equation: Thickness (segmentation) = $0.94 \times$ Thickness (Spectralis software).

DISCUSSION

THICKNESS MAPPING OF RETINAL LAYERS CAN BE USEFUL for detection and monitoring of thickness alterations in specific retinal layers associated with retinal pathologies. In the current study, application of a novel automated image segmentation technique for thickness mapping of 6 retinal layers using SD-OCT technology was reported. Thickness maps generated in normal subjects corresponded with normal retinal anatomy. Total retinal thickness derived by automated thickness mapping highly correlated

with measurements obtained by Spectralis SD-OCT commercial software. In addition, normal retinal thickness maps for 6 retinal layers were generated, intersubject thickness variability was established, and normal thickness variations in 9 macular sectors of each layer were reported.

Thickness maps of the nerve fiber layer and ganglion cell layer + inner plexiform layer displayed a minimum in the central foveal area, as expected with normal anatomy. The nerve fiber layer thickness was highest in the perifoveal retinal area (near the optic nerve head), due to the high density of nerve fiber bundles near the optic nerve head. Intersubject variability was $11 \mu\text{m}$ (19%; SD/mean), indicative of large individual variations in normal nerve fiber layer thickness. The ganglion cell layer + inner plexiform layer thickness was greatest in the parafoveal retinal area, particularly nasal to the fovea, due to the papillomacular bundle. Intersubject variability was largest in the parafoveal retinal area and on average $11 \mu\text{m}$ (12%). Intrasector thickness variability of ganglion cell layer + inner plexiform layer was largest compared to all other layers. The inner nuclear layer displayed a minimum thickness in the central foveal and intersubject variability was on average $3 \mu\text{m}$ (8%). Thickness of the outer plexiform layer was relatively uniform and intersubject variability was on average $5 \mu\text{m}$ (15%). In the central foveal area, thickness maps of the outer nuclear layer + photoreceptor inner segments displayed a maximum, which is expected anatomically, partially due to the elongated foveal cone photoreceptors. Intersubject variability was on average $9 \mu\text{m}$ (11%). Thickness variability in the photoreceptor outer segments layer was on average $7 \mu\text{m}$ (18%), indicative of large variations in photoreceptor cell structure among normal subjects. Intrasector thickness variability of the photoreceptor outer segments layer was on average $5 \mu\text{m}$, suggesting uniform thickness across all retinal areas.

Mean nerve fiber layer thickness averaged over all macular sectors was $36 \pm 7 \mu\text{m}$, comparable to $30 \pm 5 \mu\text{m}$ previously reported by TD-OCT imaging.¹⁵ Mean nerve fiber layer thickness averaged over all macular sectors, excluding the central foveal area, was $40 \pm 7 \mu\text{m}$, in agreement with measurements of $34 \pm 5 \mu\text{m}$ obtained by SD-OCT,³ but higher compared to previously reported measurements ($28 \pm 5 \mu\text{m}$)² obtained by low-resolution TD-OCT. Mean thickness of the ganglion cell layer + inner plexiform layer and inner nuclear layer averaged over all sectors, excluding the central foveal area, were $72 \pm 9 \mu\text{m}$ and $34 \pm 2 \mu\text{m}$, respectively, similar to previously published measurements of $73 \pm 7 \mu\text{m}$ and $33 \pm 3 \mu\text{m}$, respectively.³ However, mean ganglion cell layer + inner plexiform layer + inner nuclear layer thickness ($106 \pm 10 \mu\text{m}$) was higher than previously reported thickness measurements of the inner retina complex ($91 \pm 4 \mu\text{m}$).² Compared to previous studies that analyzed 6 radial TD-OCT images, inner retina thickness measurements in the current study were similar to 1 study³ and consistently higher than a second study.² The disparity in thickness

^dOoto and associates.¹¹

measurements may be attributed to differences in image resolution and segmentation algorithms. Thickness maps of the nerve fiber layer + ganglion cell layer + inner nuclear layer in the current study displayed similar thickness variations as compared to those generated by a prototype SD-OCT instrument.¹²

The pattern of thickness variations on outer nuclear layer maps in the current study corresponded well with those generated in a previous study.⁴ Mean outer nuclear layer + photoreceptor inner segments + photoreceptor outer segments thickness ($115 \pm 8 \mu\text{m}$) was higher than previously reported thickness measurements of outer retina complex (ORC) ($96 \pm 6 \mu\text{m}$), using ultra-high-resolution OCT and thickness mapping based on 6 radial scans.⁵ Since the ratio of ORC to total retinal thickness was similar in both studies, the difference in ORC thickness may be attributed to variations in segmentation algorithms in detecting the posterior retinal boundary. A recent study has established an increased measurement of total retinal thickness by Spectralis SD-OCT as compared to Stratus TD-OCT, because of a difference in detection of the photoreceptor outer segment/retinal pigment epithelium (RPE) interface.⁹

Total retinal thickness derived by thickness mapping was highly correlated with measurements obtained by Spectralis SD-OCT software, but consistently lower

(~6%). This difference may be attributed to the dissimilarity in the location of the posterior retinal boundary detected using the 2 methods. Spectralis SD-OCT software included the outer segment/RPE–Bruch membrane complex in thickness measurements,⁹ while the automated segmentation algorithm in the current study detected the inner border of the complex as the posterior retinal boundary. In the foveal area, total retinal thickness in the current study ($264 \pm 13 \mu\text{m}$) was comparable to previously reported data in normal subjects ($270 \pm 23 \mu\text{m}$).¹⁰ A comparison of total retinal thickness in each of 9 macular sectors obtained by various SD-OCT instruments^{8,11} and the current study is shown in Table 2. Despite the differences in populations, thickness measurements are similar.

In summary, a method for automated thickness mapping of 6 retinal layers is reported. Normal thickness maps for each layer were generated and thickness variabilities among subjects and macular areas were assessed. SD-OCT image segmentation and retinal thickness mapping may be limited in the presence of retinal pathologies that cause local changes in the optical properties of retinal layers and requires further investigation. Overall, the application of this technique is promising for investigating thickness changes in specific retinal layers and macular areas attributable to disease.
